Background

Background

When we use map apps like baidu, gaode, etc, they will automatically recommend the shortest route for us. However, this kind of map apps can't cover some special area, especially small indoor environment. For example, we can use Gaode to seek a route to a shopping mall. It is a pity that after we enter the mall, these apps can't help us to find specific stores any longer. Their feasible function stop here.

Game style

军工厂地图

Besides, seeking the shortest route for winning a game with fixed map is also **beyond** these apps' function.

But the maps are so **complicated** that it is hard for us to figure out the shortest escape route immediately.

Our Goals

So we'd like to develop a program that can make up for the defect we talked before, which means you can input a map like the specific locations of stores in a big mall, and ask the program to identify the shortest path for you.

What's more, except for the use we just mentioned, this program can also benefit a lot in the virtual world.

With this program, all you have to do is to prepare the specific map in advance and input your location when you want. Then you will get the best way leading to the gate as soon as possible.

The background of the image is a piece of marbled paper with a light cream base and dark, irregular veins. A solid black circle is positioned in the center-left of the frame, overlapping the marbled paper and a light gray triangular area on the left. Inside the black circle, the number '02' is written in a large, white, sans-serif font.

02

Description

Description

01 INPUT

INPUT

The input to the program is a text file. It contains comments, a start position, a goal position and a 2D map. Sentences begin with a dollar character(\$) are comment lines. The first non-comment line of that text file encodes the start position of the robot and the second non-comment line is the goal position. Those are two integer numbers separated by spaces. They encode x, y , in that order.

The second part of the input is the map. It consists of either '.' (a free cell) or 'X' (occupied cell = wall). The bottom left cell in the text file is located in the origin of the coordinate system (0, 0). The x-axis follows this line to the east (right) while the y-axis follows this column to the north (up).

The width of the map is defined by the number of characters in the line. The height of the map is defined by the number of lines in the map part.

02 OUTPUT

OUTPUT

The program has to output the map with the found path marked with the letter P. The format follows exactly the input map format, except that the found path, including the start point and the goal point, are marked with the letter 'P' instead of a '.'

03

Explanation
Of the code

Simplify the map

```
$
$ Start position, goal position and map
$
$ Start position: x, y
$ Coordinate system starts with ., . in lower left
corner
$
$ Now the actual start position:
$
6 4
$
$ Now the goal position:
$
7 6
$
$ Now follows the map (consists of only . or X)
$
.....
.....
.....
...XXXXXXX.....
...X.....X.....
...X.....X.....
...X.....X.....
.....
.....
```

```
COMMENT_MARKER = '$'
ROAD_MARKER = '.'
WALL_MARKER = 'X'
PATH_MARKER = 'P'
```

```
.....
.....
.....●.....
...XXXXXXX.....
...X...●...X.....
...X.....X.....
...X.....X.....
.....
○.....
      ↓
.....
.....
.....PPP.....
...XXXXXXXXXP.....
...X...P...XP.....
...X...P.XP.....
...X...PXP.....
.....P.....
.....
```

Core: Dijkstra's algorithm

VERTEX	SHORTEST DIST. FROM @	PREVIOUS VERTEX
a	0	
b	∞	
c	∞	
d	∞	
e	∞	

Visited = []

Unvisited = [a, b, c, d, e]

↑
current vertex

* Visit the vertex with the smallest-known cost.

* Examine its neighboring nodes, and calculate the distance to them from the vertex we are visiting.

- distance to b: $0 + 7 = 7$
- distance to c: $0 + 3 = 3$

* If the calculated distance is less than our currently-known shortest distance, update the shortest distance for these vertices.

- for node b: $7 < \infty$
 - for node c: $3 < \infty$
- We will update our table's values for these nodes' shortest distances. We'll also add a as their previous vertex.

Visited = [a]

Unvisited = [b, c, d, e]

↑
current vertex

* Two out of three of c's neighbors are unvisited, so we'll check them + their shortest paths, from the start vertex, via c.

VERTEX	SHORTEST DIST. FROM @	PREVIOUS VERTEX
a	0	
b	7 4	a
c	3	a
d	∞	
e	∞	

* We'll next head over to vertex c — remember, we need to visit the node with the smallest-known cost. Since c's cost is the smallest of our unvisited nodes, that's what we'll check next.

- distance to b: $3 + 1 = 4$

- distance to d: $3 + 2 = 5$

* Notice that the distance to b via node c is 4. This is shorter than the currently-known shortest distance in our table, which is 7.

→ We can update our shortest distance + previous vertex values for b, since we found a better path:

b	7 4	a c
---	----------------	----------------

Visited = [a, c]

Unvisited = [b, d, e]

↑
current vertex

* We check its unvisited neighbors, and calculate their smallest distance from the start, via node b.

* Since node b is the unvisited vertex with the smallest cost currently, we visit that next.

- distance to e: $4 + 6 = 10$

VERTEX	SHORTEST DIST. FROM @	PREVIOUS VERTEX
a	0	
b	7 4	a c
c	3	a
d	5	c
e	∞	

Visited = [a, c, b, d]

Unvisited = [e]

↑
current vertex

* The only node left to visit is e. However, all of its neighbors have already been visited, so there's nothing for us to examine or update here!

[a, c, b, d, e]

Pseudocode

```
Initialize all map cells with infinite distance
Initialize the start cell with 0 distance
Add start cell to wavefront (active set)
While wavefront not empty:
    select the first node
        remove node from the wavefront
        if node == goal:
            break
        for all 8 neighbors of the node:
            if the neighbor is valid and not a wall:
                neighDist = distance saved in node +
distanceToNeighbor (1 or sqrt(2))
                if neighDist < distance saved in neighbor:
                    update distance saved in neighbor with nieghDist
                    append neighbor to the wavefront (active set)
Create the path:
    starting from the goalCell select the neighbor with the lowest
distance saved
        add the selection to the path and continue with the
selection to save it's lowest neighbor till you reached the start
point
Print the map with the path
```

Optimization

Use 8 directions

```
BORDERING DIRECTIONS = [  
    Direction(dx=1, dy=0),  # Up  
    Direction(dx=0, dy=1),  # Right  
    Direction(dx=-1, dy=0), # Down  
    Direction(dx=0, dy=-1)  # Left  
]  
  
BORDERING_DIRECTION_TRAVEL_COST = 1  
  
DIAGONAL DIRECTIONS = [  
    Direction(dx=1, dy=1),  # Upper right  
    Direction(dx=-1, dy=1), # Bottom  
right  
    Direction(dx=-1, dy=-1), # Bottom  
left  
    Direction(dx=1, dy=-1)  # Upper left  
]  
  
DIAGONAL_DIRECTION_TRAVEL_COST = sqrt(2)
```

```
# Wavefront algorithm  
wavefront(active set) = [start cell]  
# To get the eight points around the middle point  
def get_neighbour_point(point, direction):  
    .....  
# Check if the point is in the map  
def point_is_in_map(point, map):  
    .....  
# Check if the point is "wall"  
def point_is_free(point, map):  
    .....  
# Label points of the determined path on the map  
def set_path_on_map(row_index, column_index, map):  
    .....  
.....
```

The background of the slide features a light-colored, marbled paper texture with dark, irregular veins. A solid black circle is positioned in the center-left area of the slide, overlapping the marbled paper and a light gray triangular shape that points towards the bottom-left corner.

Reflection &
Conclusion

THIS PROGRAM HELPS US:

- Offer point to point path planning ability for places that can't be covered by the electronic map.
- Can be used in virtual world.

DIFICIENCY:

It must start with a manual entry map.

The position also need to be manually input.
